Abstract:- The disc brake is a device for slowing or stopping the rotation of a wheel. Friction causes the disc and attached wheel to slow or stop. Brakes convert friction to heat, but if the brakes get too hot, they will cease to work because they cannot dissipate enough heat. This condition of failure is known as brake fade. Disc brakes are exposed to large thermal stresses during routine braking and extra ordinary thermal stresses during hard braking. Actual disc brake has no holes; design is changed by giving holes in the disc break for more heat dissipation. An attempt is made in this project work to modeling and analysis of disc break first the disc break is modeling and meshing by using catia V5R20 and static and modal analysis is done by ANSYS 14.0 software by using four different materials like mildsteel, Aluminium, Castiron and composite material (e-glass).

Our main aim of the project is to compare the four materials which is having least deformation and less frequency and choose the best material which is suitable for designing the disc brake.

Keywords: CATIA, ANSYS WORKBENCH, mildsteel, Aluminium, Castiron and composite material (e-glass).

1. INTRODUCTION

Brake is a device by means of artificial frictional resistance applied to moving machine member, in order to stop the motion of vehicle. The energy absorbed by brakes is dissipated in the form of heat. This heat is dissipated in the form of atmosphere.

2. PRINCIPLES OF BRAKING SYSTEM

When brakes are applied, hydraulically actuated pistons move the friction pads into contact with the disc applying equal and opposite forces on the disc. Due to the friction in between disc and pad surfaces, the kinetic energy of the rotating wheel is converted into heat which vehicle is to stop after a certain distance.

Figure 1 : Working principle of disc brake

2.1. COMPONENTS OF DISC BRAKE

- CALLIPER
- HUB
- BRAKEPAD
- PISTON MASTER
- CYLINDER

Figure 2 : Components of disc brake

CALLIPER : A disc brake consists of a cast iron disc bolted to the wheel hub and a stationary housing called caliper.

HUB : It is the central part of the wheel, rotating on or with the axle and from which the spokes radiate.

BRAKEPAD : It is a thin block of friction producing material that presses against a vehicle brake disc or rotor to enable the wheel to stop.

PISTON : A disc or cylindrical part tightly fitting and moving within a cylinder either to compress the cylinder or expanding inside the cylinder into a rectilinear motion usually transformed into rotary motion by means of a connecting rod.

MASTER CYLINDER : It converts force to pressure. Pressure is used to move brake pads into the place.

2.2. TYPES OF DISCBRAKES

- FIXED CALLIPER
- FLOATING CALLIPER
- SLIDING CALLIPER

FIXED CALLIPER : It uses one or more pistons mounted on each side of rotor .The caliper is mounted rigidly and does not move.

Figure 3 : Floating Calliper

FLOATING AND SLIDING CALLIPER : Both designs are quite similar and are lumped together. The caliper which is not held in a fixed position, moves slightly bringing the outside pad into contact with rotor. The most common type of disc brake in modern cars is single floating caliper.

Figure 4 : Sliding Calliper

3. LITERATURE REVIEW

Talati and Jalalifar et al. (2009), presented a paper on Analysis of heat conduction in a disk brake system. In this paper, the governing heat equations for the disk and the pad are extracted in the form of transient heat equations with heat generation that is dependant to time and space. In the derivation of the heat equations, parameters such as the duration of braking, vehicle velocity, geometries and the dimensions of the brake components, materials of the disk brake rotor and the pad and contact pressure distribution have been taken into account. The problem is solved analytically using Green's function approach. It is concluded that the heat generated due to friction between the disk and the pad should be ideally dissipated to the environment to avoid decreasing the friction coefficient between the disk and the pad and to avoid the temperature rise of various brake components and brake fluid vaporization due to excessive heating.

Rotor Disc of Disc Brake by using new materials to improve braking efficiency and provide greater stability to vehicle. An attempt has been made to investigate the suitable hybrid composite material which is lighter than cast iron and has good Young's modulus, Yield strength and density properties. Aluminum base metal matrix composite and High Strength Glass Fiber composites have a promising friction and wear behavior as a Disk brake rotor. The transient thermo elastic analysis of Disc brakes in repeated brake applications has been performed and the results were compared. Finally concluded that the suitable material for the braking operation is S2 glass fiber and all the values obtained from the analysis are less than their allowable values and brake Disc design is safe based on the strength and rigidity criteria

Telang A K, Rehman A, and Dixit G, Das S et.al (2013) investigated on alternate materials in automobile brake disc applications with emphasis on aluminium composites and have obtained the results that the friction coefficient of AMC is 25-30% times that of cast Iron and better wear characteristics ,the thermal conductivity of AMC can be two or three times higher than cast iron. An MMC disc could be 60 % lighter than an equivalent cast iron component. The Thermal Diffusivity, which is the rate of heat dissipation compared to that of storage, is four times that of cast iron.

4. METHODOLOGY

CATIA is mechanical design software. It is a feature-based, parametric solid modeling design tool that takes advantage of the easy-to-learn Windows graphical user interface. You can create fully associative 3-D solid models with or without constraints while utilizing automatic or user-defined relations to capture design intent. To further clarify this definition, the italic terms above will be further defined.

Figure 5 : CATIA model of Disc Brake

4.1 Modelling of a Propeller:

Pad: On exit of sketcher mode the feature is to be padded (adding material)

Pocket: On creation of basic structure further pocket has to be created (removing material)

Revolve: Around axis the material is revolved, the structure should has same profile around axis.

Rib: sweeping uniform profile along trajectory (adding material)

Slot: sweeping uniform profile along trajectory (removing material)

Loft: Sweeping non-uniform/uniform profile on different plane along linear/non-linear trajectory

4.2 Fundamentals of FEA:

The finite element method is numerical analysis technique for obtaining approximate solutions to a wide variety of engineering problems. Because of its diversity and flexibility as an analysis tool, it is receiving much attention in almost every industry. In more and more engineering situations today, we find that it is necessary to obtain approximate solutions to problem rather than exact closed form solution. It is not possible to obtain analytical mathematical solutions for many engineering problems. An analytical solutions is a mathematical expression that gives the values of the desired unknown quantity at any location in the body, as consequence it is valid for infinite number of location in the body. For problems involving complex material properties and boundary conditions, the engineer resorts to numerical methods that provide approximate, but acceptable solutions. The finite element method has become a powerful tool for the

numerical solutions of a wide range of engineering problems. It has been developed simultaneously with the increasing use of the high- speed electronic digital computers and with the growing emphasis on numerical methods for engineering analysis. This method started as a generalization of the structural idea to some problems of elastic continuum problem, started in terms of different equations.

4.3 Meshing of Propeller Blade:

The solid model is transfer to the ANSYS WORKBENCH software.with the required commanding the mesh is generated for the model.Generally there two types of meshes are there ther are Tetrahedral Mesh.

(i) Hexahedral Mesh

The Tetrahedral mesh is a polygon consists of four triangular faces three of them are meet at a pointcalled as vertex.It has 6edges and 4 vertices.In case of hexahedral mesh it has 12 edges and 8 vertices.For the accuracy of the solution hexahedral gives the exact result.In the ANSYS software the internal command setting can be available for mesh generation.

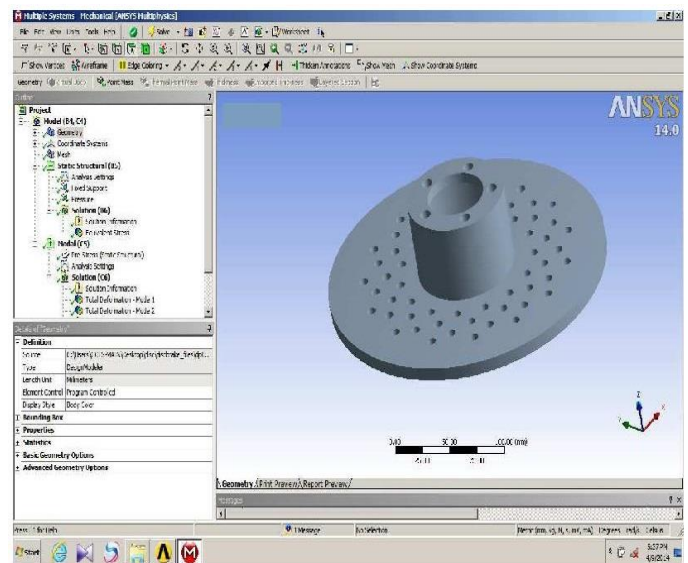

Figure 6 : Fine meshed model of Disc Brake

4.4 Structural Analysis:

Structural analysis is the most common application of the finite element analysis. The term structural implies civil engineering structure such as bridge and building, but also naval, aeronautical and mechanical structure such as ship hulls, aircraft bodies and machine housing as well as mechanical components such as piston, machine parts and tools.

6. CONCLUSIONS :

It is concluded from the above study that using CATIA V5 R20 software design and modeling become easier. Only few steps are needed to make drawing in three dimensions, some can be imported to Ansys for analysis. Disc brake made of four different materials mild steel, all alloy, cast iron and composite material (e-glass) are analysed. Max pressure is found at the centre of disc brake. This is equal for all materials.

The disc brake is done on both static structural and modal analysis (with and without pre stresses). Depending upon on frequency and pressure values, the max frequency and pressure is found at Al alloy, and minimum frequency and pressure is found at composite material.

By comparing the above table, mild steel frequency and pressure will varies but the mild steel has good corrosive resistance and the aluminium values also increasing slightly but it has good thermal conductivity and the cast iron has good strength.

From the four materials e-glass has good properties and it has less frequency and less deformation. So, e-glass is the best material for designing the disc brake. Although e-glass has less deformation but it is costlier. If we reduce the cost of e-glass it is more economical to use with long life. Hence, composite material is suitable material for designing disc brake.
